

Data Science – Project Guidelines

Typically, your project will go through following phases.

1. Data selection followed by data preparation (encoding, embedding, handling outliers, noisy data, missing values etc).
 2. Define your problem statement. You must perform EDA and literature survey, to support the novelty of your problem statement and it is different from existing problems studied on the same dataset (if any).
 3. Get inferences from the data using statistical analysis such as hypothesis testing. Understand and design your tests that are relevant to your problem statement. Conduct a comprehensive comparison with other types of tests. Identify which findings matters the most for your problems.
 4. Train and validate some simple ML models (regression, classification or clustering) on the dataset. Apply scaling techniques before training and compare its performance before and after such scaling methods.
-
- To begin the project, form a team of at most six members. You must share your team members' names, email addresses, and roll numbers by 1st September in this [Google form](#).
 - You will be assigned a TA as a mentor whose job is to advice you with your queries.

All the best!
